

# RECOMMENDED THAWING PROCEDURE

---

Place bag of plasma in water not exceeding 40°C to 45°C (the temperature of a shower that you can stand in comfortably). If the water is too hot, it will damage the proteins! (See photographs below)

As the plasma thaws and the water cools, you can ADD MORE HOT WATER, but avoid hot water from the faucet coming into direct contact with the bag of plasma.

It is extremely important that the plasma is brought to body temperature to minimize the presence of cryoprecipitates. It will take a minimum of 30-40 minutes to complete the thawing procedure correctly.

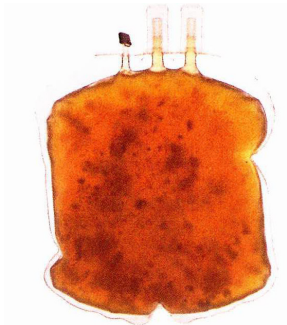

## DO NOT MICROWAVE

Only infuse through a blood administration set that contains a filter and **DO NOT MIX** with any other fluids or drugs. Do not use this product if it contains excessive amounts of precipitates.

### THAWED CORRECTLY

### THAWED INCORRECTLY
